## SOFTWARECOO

Travel Radio Australia and we're here at the fantastic MAPIC conference in Cannes in France and I have the COO of Over the Reality Software, it's Diego de Tommaso and they make software for you if you're going to a shopping center you can actually scan a QR code and find out exactly where you are and where you're going it's a fantastic system. Diego welcome to the program. Hi, nice to miss you, thanks for having me.

Now Diego this software is really world-beating and really innovative, tell us about how it all works. Sure, yeah basically what we're building it's saying quickly Google Maps for Indoor. So basically we allow people to understand where they are in large spaces and we work, we started with malls but actually this technology is usable on any big indoor structure.

The novelty and the way it works is that this is all based on computer vision so we don't ask the building owner to install any hardware. What we do instead, we just map the location with Kansamer 360 cameras. At the moment we use Insta360 X6, that is a $700 hardware basically affordable for anybody.

We just walk inside of the building, we generate a 3D map of the location and once the location is met we can tell where smartphones and in the future smart glasses are in space very precisely, not only where they are but also where they are looking. Thanks to this capability we can actually allow to create an indoor navigation system as familiar as these Google Maps to navigate inside of buildings. Now it's not just for shopping centers I would imagine, you could do this for all sorts of places like theme parks, ski resorts or all over the place, right? Absolutely, yes, airport stations, hospitals, every complex building to navigate is basically the target for this technology.

And what's your background Diego, how did you come to be in this and was it your idea to get this going? Our company was founded in 2019 actually back in the days we were more I would say a metaverse company working with augmented reality but in the last years we changed our value proposition and came to what we call physical AI and so our main business is actually data collection so we scan physical locations and we license this data to AI labs. So since we built a very robust pipeline to capture places we thought that basically we could deploy also this technology with a vertical application and we see the indoor navigation as I mean an important pain point for big buildings and we thought that with this kind of project we could combine both our ability to map large locations with our competence in augmented reality so we can build a self-contained solution to actually navigate a large location intuitively. Now we've all been there we've all been in a big shopping center and you're on one floor and you think oh I'm at this shop and then you get completely lost with your system it's so easy because once you scan that QR code on your phone will tell you exactly where you are so I suppose you can punch in the name of a shop and it will just guide you there.

Yeah exactly you can write down the name of the shop or looking for a product that is connected

of course to the shop and you will be guided exactly there. The QR code can be placed everywhere so we don't rely on the QR code to understand where you are it's just a way to trigger the experience so you can also for example launch it for the software with the sample web link and a very important thing cause is that we don't require to download any app so we also remove that friction everything happens just with a trigger of the link both with iOS and Android. It's a brilliant system and what are the apart from shopping centers what other areas are you getting into? Ira we're looking at is airports and also complex building structures for example if you think that Saudi Arabia or Dubai where basically in summer is impossible to go out many of these buildings are connected through tunnels and so on and basically their GPS doesn't work at all so if you want to navigate this also large compounds let's say this solution is very handy because basically you can navigate through these mates and just by using this app understanding what is best route to get to your destination and how does that work does it work sort of offline does it load up the information onto your phone offline so say like if you're in a tunnel would it still work oh no that's that's a good point so basically you the only caveat that of course you need to have internet connection so that's the only thing required so if there is no internet connection that is not gonna work yet if you already launched the experience so basically you already charge your destination then it will guide you through even if connection is disrupted or interrupted but at some point you need the connection again of course now what's your experience here at mappick I suppose you've had a lot of interest for your products here from all the big shopping centers that sort of thing absolutely yeah I mean we had more interest than we expected actually we was thinking that we were gonna go to talk with the people but actually many people came to us and not only for shopping centers but few people also from big structures like airports and buildings and complex compounds like for example in Saudi Arabia and in Dubai so I mean it's very positive experience here how can people find out more about your system online if they are shopping center managers or owners how can they find out oh yes they just can head to business.ovr.ai and they will see the solution how it works integrating also with the map I didn't mention that basically not only we provide the service but on top of that we also provide the 2d map of the location that you can actually distribute on other touch points so yes if you are in the place you were gonna navigate with a smartphone but if you want to plan or understand how the location is built you will have the same map into the plan your visit basically and all of this is part of the future that because in the next 10 years this sounds a bit space-agey now but all this will be very normal in the next 10 years absolutely I mean and by the way we see a future not so far away maybe in one two years where affordable smart glasses will be wired by everybody and for example that is a killer application for smart glasses also because in that case you will have the projection on your lenses on how to reach the location seamlessly without having to take out your phone and the technology business the same it's just if you think about that as my glasses just like a smartphone but instead of having a screen you're looking at you look through it but still you have a camera you have the GPS you have the IMU that to have the system understand where you are in space so it's like a heads-up display on an aircraft so or a fighter jet pilot who can look forward and see everything because that is one of the big problems people staring down at their

phones all the time and that's bad for posture bad for all that sort of thing but but these new glasses coming in and I think they will be very normal in the next few years it's better for everybody I think yeah probably yes is one of the times that this the technology basically will kind of disappear in the background the while yes as you mentioned right now we see all the people cured of the looking at their smartphones finally we will look back in front of us again yeah they come back that can't be a bad thing because it's bad for people's posture and and they walk into things and also also things well it's a fascinating new world out there Diego de Tommaso and and thank you for doing this over the reality software thank you very much for being part of the program thanks to you for taking the time to interview me
